

## Explore some Fundamental Symbolic Computing syntax:

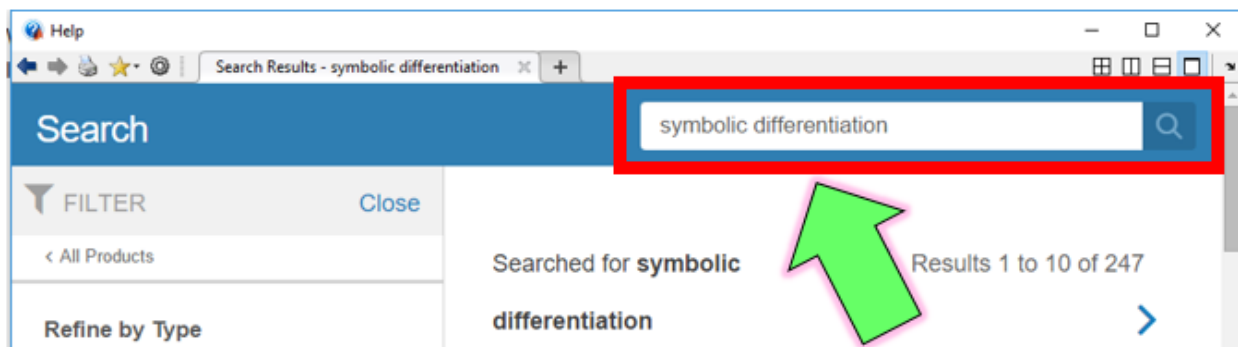

We'll look at some fundamental syntax (patterns) for doing **symbolic** computing. We'll look at how to create and manipulate symbolic expressions. Specifically we, we'll:

- create symbolic expressions
- create symbolic functions
- Plot symbolic expressions
- Differentiate
- Integrate
- computer Laplace transforms
- Solve ODEs

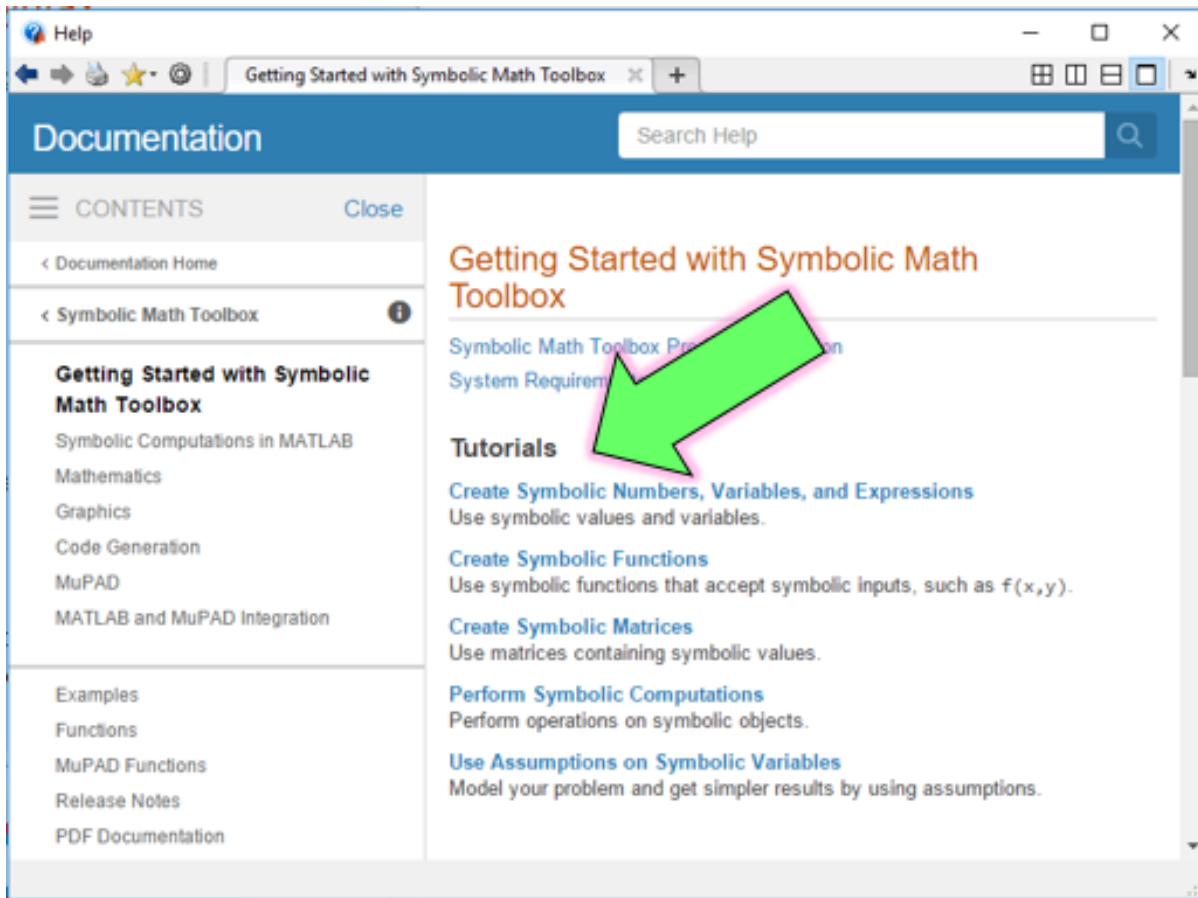

While you're doing this tutorial, don't forget to leverage the MATLAB help browser:

Look for this icon on the MATLAB desktop and click on it often ! The help browser lets you search using "plain english" keywords. For example, if you wanted to know how to differentiate symbolic expressions, you could start by typing in this search:

The Help Browser also has a collection of "Getting started" Tutorials !

10-Jan-2017 : Bradley Horton, [bradley.horton@mathworks.com.au](mailto:bradley.horton@mathworks.com.au)

**A symbolic expression: ( aka a `sym` )**

```
syms x y theta
```

And now you can create a symbolic expressions using that `sym` variable:

```
f = exp(-y)/x + 3*x^2
```

f =

$$\frac{e^{-y}}{x} + 3x^2$$

```
R = [ cos(theta), -sin(theta), f;
      sin(theta), cos(theta), 0;
      0,          0,          1;
    ]
```

R =

$$\begin{pmatrix} \cos(\theta) & -\sin(\theta) & \frac{e^{-y}}{x} + 3x^2 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Using familiar MATLAB indexing syntax, we can extract the 1st row and 3rd column of the R matrix:

```
some_expression = R(1,3)
```

```
some_expression =
```

$$\frac{e^{-y}}{x} + 3x^2$$

If I have a symbolic expression and I want to evaluate it with some numerical inputs, you would use the **subs()** function. Eg: consider the expression stored in g :

```
g = 5*x + 7
```

$$g = 5x + 7$$

If I want to evaluate this expression with x=2, then we'd use the **subs()** function:

```
some_value = subs(g,x,2)
```

```
some_value = 17
```

### A symbolic function: (aka a **symfun**)

Now create some sym variables

```
syms x y
```

We can construct a **symfun** symbolic function variable using this syntax:

```
f(x,y) = 5*x + (x^2)*(y^2)
```

$$f(x, y) = x^2 y^2 + 5x$$

So evaluate:

- $f(x=2, y=5)$ : and this should give us:  $2*5 + (4)*(25) == 110$

```
Sf_val = f(2,5)
```

```
Sf_val = 110
```

If I wanted to "extract" the formulae (or expression) used to define the SYMFUN, here's how:

```
some_expression = formula( f )
```

```
some_expression =  $x^2 y^2 + 5 x$ 
```

And because we have an expression we can use the `subs( )` function:

```
subs(some_expression, {x,y}, {2,5})
```

```
ans = 110
```

## Plotting 2D functions : $y = f(x)$

A function or expression of the form  $f(x)$ , can be plot/visualized using the `fplot( )` function:

```
syms X
y = 20 + X^2 - 10*(cos(2*pi*X) + 1 );
```

Now plot it using the `fplot( )` function ... and put add some annotations:

```
figure;
    fplot(y, [-5 5]);

    title('HELLO')
    xlabel('X'); ylabel('Y'); grid('on')
```

and add another function to the plot

```
syms a
z(a) = a^2 + 10;

hold on
fplot(z, [-5 5], '-r')
```

## Plotting 3D functions : $Z = f(x, y)$

To plot a surface, use the `fsurf()` function:

```
syms x y
f = 3*(1-x)^2*exp(-(x^2)-(y+1)^2)...
    - 10*(x/5 - x^3 - y^5)*exp(-x^2-y^2)...
    - 1/3*exp(-(x+1)^2 - y^2);
```

Now plot it:

```
figure;
h = fsurf(f, [-3 3]);
```

Annotate the plot

```
xlabel('x'); ylabel('y'); zlabel('z');
title_latex = ['$ latex(f) $'];
title(title_latex, 'Interpreter', 'latex', 'FontSize', 14)
```

Put a frame around the plot

```
a = gca;
a.Box = 'on';
a.BoxStyle = 'full';
```

$$3e^{-(y+1)^2-x^2}(x-1)^2 - \frac{e^{-(x+1)^2-y^2}}{3} + e^{-x^2-y^2}(10x^3 - 2x + 10y^5)$$

### Finding Analytical solutions:

**a.) Integration:** Let's do this:  $f(t) = \int e^{-3t} \sin(5t) dt$

```
syms t
dfa_dt = exp(-3*t)*sin(5*t); % the integrand

fa      = int( dfa_dt, t)      % <----- and the INDEFINITE integral is
```

$$fa = -\frac{e^{-3t} (5 \cos(5t) + 3 \sin(5t))}{34}$$

**b.) Differentiation:** Let's do this:  $f(t) = \cos(2t)e^{5t} \rightarrow$  so what is  $\frac{df}{dt}$  ?

```
fb      = cos(2*t)*exp(5*t);
dfb_dt = diff(fb, t)        % <----- and the derivative is
```

$$dfb\_dt = 5 \cos(2t) e^{5t} - 2 \sin(2t) e^{5t}$$

**c.) Laplace transforms:** Let's do this:  $f(t) = \cos(2t)e^{5t} \rightarrow$  so what is  $F(s) = \mathcal{L}\{f(t)\}$  ?

```
syms s
my_ft = cos(2*t)*exp(5*t);

my_Fs = laplace(my_ft, t, s)
```

$$\text{my\_Fs} = \frac{s - 5}{(s - 5)^2 + 4}$$

And let's do the inverse too:

```
fc = ilaplace(my_Fs, s, t)
```

$$f_c = \cos(2t) e^{5t}$$

**ODEs:** solve this  $x(t) + 4.\dot{x}(t) + 100.x(t) = 200.u(t - 5)$  with  $\begin{cases} x(0) = 5 \\ \dot{x}(0) = 0 \end{cases}$

```
% define some SYMBOLIC variables
syms t x(t)

% construct the SYMBOLIC 2nd order ODE
f = 200*heaviside(t-5);
EQ = 1*diff(x,2) + 4*diff(x,1) + 100*x == f
```

$$\text{EQ}(t) = \frac{\partial^2}{\partial t^2} x(t) + 4 \frac{\partial}{\partial t} x(t) + 100 x(t) = 200 \text{heaviside}(t - 5)$$

Now find the analytical solution:

```
% now find the analytical solution applying our IC's
dx(t) = diff( x(t), t);

x = dsolve( EQ, x(0)==5, ...
            dx(0)==0, ...
            'IgnoreAnalyticConstraints', false);

x = simplify(x)
```

$$x = 2 \text{heaviside}(t - 5) + 5 e^{-2t} \cos(4 \sqrt{6} t) + \frac{5 \sqrt{6} e^{-2t} \sin(4 \sqrt{6} t)}{12} - 2 \text{heaviside}(t - 5) e^{-2t} e^{10}$$

where

$$\sigma_1 = 4 \sqrt{6} t - 20 \sqrt{6}$$

```
% compute the velocity (because we can)
```

```
v = diff(x,t)
```

v =

$$2\delta(t-5) - \frac{125\sqrt{6}e^{-2t}\sin(4\sqrt{6}t)}{6} - 2\delta(t-5)e^{-2t}e^{10}\cos(\sigma_1) - \frac{\sqrt{6}\delta(t-5)e^{-2t}e^{10}\sin(\sigma_1)}{6}$$

where

$$\sigma_1 = 4\sqrt{6}t - 20\sqrt{6}$$

Plot the solution

```
figure;
subplot(1,2,1)
    fplot(x, [-0.01, 10]);
    xlabel('t (secs)'); ylabel('(m)');
    grid('on'); legend('x(t)')
subplot(1,2,2)
    fplot(v, [-0.01, 10]);
    xlabel('t (secs)'); ylabel('(m/sec)');
    grid('on'); legend('v(t)')
```

*FYI: a symbolic expression can be converted into LaTeX code using the `latex()` function. You could then copy and paste this into your own latex files OR into a latex viewer(eg: [QuickLaTeX.com](https://www.quicklatex.com)) in your web browser(remember to include the \$ \$ )*

```
latex(x)
```

```
ans = 2\, \mathop{\mathrm{heaviside}}\nolimits!\left(t - 5\right) + 5\, \mathrm{e}^{\left\{- 2\, t\right\}}\, \cos\left(t\right)
```

## Converting symbolic expressions into MATLAB functions:

Say we have a symbolic expression:

```
syms x y  
  
z = x + y;
```

We can convert this symbolic expression into a reusable MATLAB function using the function `matlabFunction()`:

```
matlabFunction( z,  
               'File','my_func', ...  
               'Vars', {'x', 'y'});
```

```
% look at the autogenerated file  
dbtype('my_func.m')
```

```
1 function z = my_func(x,y)  
2 %MY_FUNC  
3 % Z = MY_FUNC(X,Y)  
4  
5 % This function was generated by the Symbolic Math Toolbox version 7.1.  
6 % 31-Jan-2017 11:41:14  
7  
8 z = x+y;
```

## Converting symbolic expressions into SIMULINK blocks:

We can also convert symbolic expression into Simulink blocks using the function `matlabFunctionBlock()`:

```
FILENAME      = 'SIM_bh_autogen_z';  
BLOCK_NAME    = [FILENAME, '/my_euler_rates'];  
new_system(FILENAME)
```

```
open_system(FILENAME)
```

```
matlabFunctionBlock(BLOCK_NAME, z, 'Vars', {'x', 'y'} );
```

```
Evaluating callback 'PostLoadFcn' for simulink  
Callback: setsysloc_simulink(bdroot)  
Evaluating callback 'LoadFcn' for simulink/Sources/Waveform Generator  
Callback: set_param(gcb,'LoadFlag','1');
```

```
Evaluating callback 'LoadFcn' for simulink/Sources/Signal Builder  
Callback: sigbuilder_block('load');  
Evaluating callback 'LoadFcn' for simulink/Sinks/XY Graph  
Callback: sfunxy([],[],[],'LoadBlock')  
Evaluating callback 'LoadFcn' for simulink/Model-Wide Utilities/Model Info  
Callback: slcm LoadBlock;  
Evaluating callback 'LoadFcn' for simulink/Math Operations/Slider Gain  
Callback: slideg Load
```

## A Case Study - part 1: Deriving the equations of motion

Look at a simple application of Lagrange's equation ... say for simple spring, mass mechanical system

(with NO damping):  $\frac{d}{dt} \frac{\partial L}{\partial \dot{x}} - \frac{\partial L}{\partial x} = Q$

```
clear; clc
```

Define some Symbolic variables that we can play with:

```
syms t x(t) m k b F  
syms THE_X THE_XD THE_XDD  
actual_list = [ x, diff(x,t), diff(x,t,2)];  
HOLDER_list = [ THE_X, THE_XD, THE_XDD];
```

Define our system Lagrangian and Generalised force:

```
v = diff(x,t); % velocity  
KE = 0.5*m*v^2; % KINETIC energy  
PE = 0.5*k*x^2; % POTENTIAL energy  
Q = F - b*v; % total NON conservative forces for deltaX  
L = KE - PE % our Lagrangian
```

$L(t) =$

$$\frac{m \left( \frac{\partial}{\partial t} x(t) \right)^2}{2} - \frac{k x(t)^2}{2}$$

Now let's start applying Lagrange's equation  $\frac{d}{dt} \frac{\partial L}{\partial \dot{x}} - \frac{\partial L}{\partial x}$  :

```
L_new = subs(L, actual_list, % OLD_LIST NEW_LIST HOLDER_list)
```

$$L_{\text{new}}(t) = \frac{m \dot{x}^2}{2} - \frac{k x^2}{2}$$

Our 1st piece is:  $\frac{\partial L}{\partial x}$

```
dLdx = diff(L_new, THE_X)
```

$$dLdx(t) = -kx$$

Our 2nd piece is:  $\frac{\partial L}{\partial \dot{x}}$

```
dLdxdot = diff(L_new, THE_XD)
```

$$dLdxdot(t) = m \dot{x}$$

Our 3rd piece is:  $\frac{d}{dt} \frac{\partial L}{\partial \dot{x}}$

```
dLdxdot = subs(dLdxdot, HOLDER_list, % OLD_LIST NEW_LIST actual_list )
```

$$dLdxdot(t) = m \frac{\partial}{\partial t} \dot{x}$$

```
dt_of_dLdxdot = diff(dLdxdot, t)
```

$$dt\_of\_dLdxdot(t) = m \frac{\partial^2}{\partial t^2} x(t)$$

Now put it all together:

```
our_EOM_LHS = dt_of_dLdxdot - dLdx
```

```
our_EOM_LHS(t) =
```

$$m \frac{\partial^2}{\partial t^2} x(t) + \text{THE}_X k$$

```
our_EOM_RHS = Q
```

```
our_EOM_RHS(t) =
```

$$F - b \frac{\partial}{\partial t} x(t)$$

```
our_EOM = (our_EOM_LHS == our_EOM_RHS)
```

```
our_EOM(t) =
```

$$m \frac{\partial^2}{\partial t^2} x(t) + \text{THE}_X k = F - b \frac{\partial}{\partial t} x(t)$$

```
our_EOM = subs(our_EOM, % OLD_LIST NEW_LIST
               actual_list, HOLDER_list)
```

$$\text{our\_EOM}(t) = \text{THE}_X k + \text{THE}_{XDD} m = F - \text{THE}_{XD} b$$

Now solve for  $x$ :

```
the_expression_for_XDD = solve(our_EOM, THE_XDD)
```

```
the_expression_for_XDD =
```

$$-\frac{\text{THE}_{XD} b - F + \text{THE}_X k}{m}$$

And now create a Simulink block for this expression:

```
Command Window
>> the_expression_for_XDD
the_expression_for_XDD =
-(THE_XD*b - F + THE_X*k)/m
```

```
function X_DOT_DOT = THE_X_DD_SYS(F,m,b,k,THE_X,THE_XD)
%#codegen
% This function was generated by the Symbolic Math
% Toolbox version 7.1. 11-Jan-2017 08:14:10
X_DOT_DOT = -(-F+THE_XD.*b+THE_X.*k)./m;
```

```
MODEL_NAME = 'SIM_SMD_WILL_BE_DELETED';
close_system(MODEL_NAME,0)
new_system(MODEL_NAME)
open_system(MODEL_NAME)

matlabFunctionBlock([MODEL_NAME,'/THE_X_DD_SYS'], the_expression_for_XDD, ...
                   'Vars', {F, m,b,k,THE_X,THE_XD}, ...
                   'Outputs', {'X_DOT_DOT'});
```

## A Case Study - part 2: Simulating the model

Let's use the model that we just derived, and implement it in Simulink - where we'll numerically solve it. The parameters that we'll use for this Numerical simulation are:

$$x(t) + 4.\dot{x}(t) + 100.x(t) = 200.u(t - 5)$$

- with
- $x(0) = 5$
  - $\dot{x}(0) = 0$

Have a look at our Simulink model .... and NOTE how we use the integrator blocks to

integrate:  $x \rightarrow \frac{1}{s} \rightarrow \dot{x} \rightarrow \frac{1}{s} \rightarrow x$

```
open_system('bh_a_spring_mass_model')
```
